Chapter 1 – Introduction

1.1 Motivation for a mud crab data collection system in Indonesia

In recent years, the concept of ‘sustainability’ has become an important focus of fisheries management, but is hard to define and interpretation of the concept continues to evolve (Rice 2014). It is generally accepted that a fishery must fulfill three sustainability dimensions to be considered sustainable: ecological, economic and social (Garcia & Staples 2000). The three dimensions may be defined as follows:

- ecological dimension: the stock biomass should be greater than a minimum reference level
- economic dimension: the individual vessel profit should be greater than a minimum reference level
- social dimension: there must be a minimum level of employment and activity (Martinet et al. 2007).

Additional requirements relating to bycatch of non-target species and environmental impacts can be included when necessary (Jacquet et al. 2009). Continuous data collection systems are required to evaluate the status and progress of the three dimensions of sustainability. This protocol aims to contribute towards data collection activities for the mud crab fisheries of Indonesia, so that progress towards achieving sustainability can be monitored and improved.

The global demand for sustainably-sourced seafood is increasing as certification schemes and consumer recommendation lists influence consumers’ preferences (Belson 2012). The European Commission has regulations stipulating a traceability system as a requirement for food producers and a catch certification scheme to combat the import of IUU fish (EC 2009; EC 2008). In the US, the 2011 Food Safety Modernization Act (Anon 2011) allows the Food and Drug Administration to order the establishment of food product tracing systems. To maintain Indonesia’s position as a competitive player in the global seafood market it is advised that its products begin a conversion process towards sustainability and eventual certification of sustainability. Such a certification process can only be conducted when a high level of knowledge exists regarding annual catch estimates, separated by gear and species, operational catch and effort data, size distribution of the stock and general health of the stock and the ecosystem. This data is usually limited within Indonesian fisheries and it is important that data collection processes are improved.
Despite referencing a ‘sustainable approach’ to fisheries resource management in its Development Plan, Indonesia has a poor record of implementation and enforcement and is supporting expansion rather than following the precautionary approach to fisheries, the ecosystem approach to fisheries or improving stock sustainability. Regulations from 2004 cover development and resource use within Indonesian archipelagic waters and within the Exclusive Economic Zone (MMAF 2004b; MMAF 2004a). National regulations are established and to monitor the success/progress of these regulations, robust data collection is required. Regulations relevant to this protocol include:

- Ministerial Regulation No.1/2015: outlaws capture of berried mud crabs and establishes a minimum carapace landing size for of 15cm. All catches of dead berried or undersized individuals must be reported (MMAF 2015)

Monitoring the progress and success of this regulation requires robust data collection activities. Fisheries management in Indonesia has developed into a decentralised system, whereby individual regions can introduce region-specific regulations. To coordinate management of the stocks at a national level, the government must have information from the different regions. Each region should have a number of data collection sites, providing sufficient sampling coverage to contribute to national management plans. Efforts should be made to coordinate and consolidate the data from each region. The national regulation, the regional decentralisation and the market demand for sustainably-sourced seafood motivate the need for improved data collection systems in Indonesia. This need exists in both the commercial and artisanal fisheries as also in the various gear differentiated fisheries. This protocol focuses on data collection for the mud crab, *Scylla serrata*. The associated staff training protocol (available from the IMACS website) should be consulted for detailed information on the duties of field staff.

1.2 Objectives of this data collection protocol

This protocol has been commissioned by Masyarakat dan Perikanan Indonesia, MDPI, and the IMACS program under USAID. This document is a guide for the data collection process at mud crab, *Scylla serrata*, landing sites within Indonesia. It includes: Standard Operating Procedures for recording data on fishing ground, carapace width, sex and maturity level and bait data (Chapter 2); instructions for the data collection process (Chapter 3); and the data collection forms.

This protocol has the following objectives:
• Ensure a set of standards are in place for the data collection process for mud crab in Indonesia; that this data is collected in a uniform way, that transferability of this data is ensured and that it is done in a cost efficient method

• Allow fishery managers, government agencies, regional fishery management councils and private industry to gain access to high quality data on mud crab catches in Indonesia and to use this information improve Indonesian mud crab management

In achieving the above objectives it is anticipated that the following primary objectives may also be achieved. These objectives address scientific, management and market related issues relevant to Indonesian waters:

• Improve existing knowledge within Indonesia and the wider scientific community on a small but important fishery in Indonesian.

• Use the improved knowledge to better understand stock dynamics, changes occurring due to environmental factors, such as climate change, and to adapt to these changing circumstances with appropriate management measures

• Catalogue the encounters (if any) this fishery has with endangered, threatened and protected species and develop strategies to minimize the impact of fishing activity on these species

• Ensure ecosystem and habitat functioning and resilience by increased knowledge and adaptive decision making

• Acquire additional information on the associated bycatch and make relevant decisions to minimize the indirect effects on these species/stocks

• Ensure that sustainable management practices are implemented to profile the stock correctly, ensuring catch advice adheres to sustainable and precautionary guidelines, progressing towards a sustainable mud crab fishery in Indonesia

• Increase local government involvement in the data collection process by capacity building and creating data collection networks

• Ensure that the management process takes financial as well as food security matters into consideration when making decisions on catch allowances,

• Transfer knowledge and background of the data collection process to various stakeholders involved in the mud crab supply chain, with the aim of developing ownership and eventual acceptance within the community

• Support Indonesian mud crab achieve management and sustainability levels required for eco-certification, enhancing its competitiveness in the global market
Maximize/maintain profits from mud crab fisheries while considering ecological limits

1.3 Background to the mud crab fishery in Indonesia

Mud crabs, *Scylla serrata*, can tolerate low salinity levels and can respire out of water, thus making them adaptable to habitats experiencing tidal cycles of salinity and water levels, such as mangroves. They are found in all mangrove regions of Indonesia, with Northern Sumatera, Eastern Java and Eastern Kalimantan being the most important areas historically (BOBP 1991). The largest mangrove area in Indonesia is in West Papua, where production has increased in recent decades and women conduct the fishing activity rather than men. The mud crab fisheries are important, small-scale fisheries throughout Australia and southeast Asia and are gaining importance as an aquaculture product (Mirera 2011). Crabs are sold to local markets but the highest demand is as a live export product to other Asian countries, particularly China. Suppliers buy the crabs from local fisherwomen for between 20,000-25,000Rp/kg. The fishing season is usually from January to July, with the highest market demand from August to December, from Chinese buyers.

Mud crabs are caught using baited traps and there is thought to be little associated bycatch. The traps are known locally as ‘*bubu*’, with each fisherwoman having between 5-10 traps, catching three to five crabs per trap per day. The dimensions of the collapsible traps are typically 40cm x 30cm x 20cm, with a mesh size of 1 inch. The fisherwomen use small vessels, typically <3m in length. Fishing activity for mud crab is restricted to coastal mangrove areas, with the crabs usually remaining in site-specific populations, burrowing below the mean low water level (FAO 2011). Mud crabs are a robust species, surviving trap-induced physical damage, although post-molts suffered more damage than inter-molt individuals (Butcher et al. 2012). Mud crab fisheries are small-scale and coupled with the narrow range of crab movements, it could be possible to develop site-specific management measures for this species (Ewel 2008; Dumas et al. 2012).

1.5 I-Fish database system and Data Management Committees

Given the volume of data that can be collected to inform fisheries management, a database system has been developed to store the collected data and make it easily available to different types of stakeholders. This system, termed I-Fish (Indonesian Fisheries Information System), aims to inform fisheries management planning at district, provincial and national
levels, and address the urgent need for an effective and flexible data management platform in Indonesia. I-Fish aims to align with national fisheries data standards, as well as with Marine Stewardship Council (MSC) requirements. In this way, I-Fish provides a transparent tool for data entry, storage and processing, fulfilling an essential need for fisheries under consideration for MSC certification. I-Fish is a comprehensive system for enabling the private sector to collect valid and verifiable data required by the government in order to manage fisheries sustainably. Involvement of the private sector— including fishers, traders, fishing companies, and exporters—provides near real-time data about the fishery, and assists governments to target resources where they are needed most.

To ensure I-Fish data transparency and promote collaboration amongst stakeholders, Data Management Committees, DMCs are established as co-management initiatives. DMCs focus on data from artisanal fisheries, such as BSC fisheries. The committee aims to achieve a complete representation of stakeholders to the fishery in the target area, and if necessary to support a rotational system of membership. The committees are an efficient way to coordinate data management between government officials, representatives of the fishing industry, and researchers. Through the DMCs it is expected that these stakeholders gain an informed and shared understanding about the status of the BSC stock in a local region.

The mission of the DMCs is to support and contribute to the collection and analysis of data relating to catch composition, fishing grounds and effort so as to identify specific patterns within the fishery. A summary of this data shall be published and disseminated to DMC members and stakeholders. Fishery targets can be suggested based on the shared use of the data, stakeholders can be informed of the implications of the data analysis and the information can be integrated into local management decisions. The tools and capacity to contribute to management of the fishery are then developed in the DMC members, who can help sustainably develop and manage the fishery.
Figure 1. The data flow for the I-Fish approach. A. Sustainability facilitators collect the data from fishermen and suppliers, in both the port sampling form and the monthly unloading form. B. The data is entered into a computer and verified by the field supervisor. C. Once the data has been verified it is uploaded into the I-Fish database where it can be accessed by stakeholders. D. Representatives of the Data Management Committees, DMCs, can access and download the data from I-Fish. E. The analyses data is presented and discussed at the DMC meetings by various stakeholders.
Chapter 2 – Standard Operating Procedures

This chapter covers seven Standard Operating Procedures, SOPs, which can support field staff in their data collection activities. These SOPs should be referred to in the first instance should there be any problem with data collection in the field. If the problem can not be resolved using the relevant SOP, the site supervisor/manager should be contacted. The solution to the problem should then be incorporated into the relevant SOP.

2.1. Standard Operating Procedure I – Fishing gear and grounds

Mud crabs are caught using baited traps, locally known as ‘bubu’. There are two variations of the traps, either rectangular or oval-shaped (Figure 1 for rectangular version). Crabs enter through each end, fall into the main chamber of the trap and are unable to escape. The focus for data collection activities as a sampling trial is currently on two villages in the Arguni Bay, West Papua (Figure 2). In Arguni Bay, fishing activity occurs at least 50m offshore of the mangrove, extending to ~1km offshore. Consequently, maps developed for data collection purposes need to be site-specific. In applying this data collection protocol to other sites besides Arguni Bay, site-specific maps should be developed to facilitate data collection.

Figure 1. Rectangular trap used for catching mud crabs.
Figure 2. A. Arguni Bay in West Papua, highlighted with red box. Kaimana is the main town in this region. B. Enlarged map of Arguni Bay. Villages, Tugarni and Urissa, where data collection will be conducted highlighted with stars.

Separate maps were created for the data collection activities in Urissa and Tugarni (Figure 3). For both maps a grid was overlaid, with each square measuring ~500m each side. The Urissa grid is labeled vertically from 1 to 11 and horizontally from A to G. The Tugarni grid is labeled vertically from 1 to 12 and horizontally from A to I. When recording the fishing location for either Urissa or Tugarni, the fisherwoman points out all squares where she placed traps. For each square the letter is recorded first followed by the number, i.e. a fisherwoman from Urissa may have fished in squares D5 and D6, and a fisherwoman from Tugarni may have fished in squares B6 and C6.

STILL IN PROGRESS

Figure 3. Enlarged map for Urissa (left map, red star) and Tugarni (right map, red star) fishing areas with grid recording systems.
2.2. **Standard Operating Procedure II – Species Identification**

The site supervisor is responsible for ensuring all individuals are identified to species level. If there is doubt as to the identification of a species the following steps should be taken:

- The fisherwomen/supplier should be consulted as to the identification of the species. This may result in the species being identified with a local name, which should be recorded and reported to the supervisor. The supervisor should ensure the new species is included in this protocol.
- If the species cannot be identified a detailed description of external features of the species should be recorded and a picture taken for reference. This should be forwarded to relevant supervisors/managers, etc.

1. *Scylla serrata* / Mud crab / Mangrove crab / Kepiting bakau / MUD

*Scylla serrata* is a portunid crab, meaning that fourth pair of legs are flattened into paddle-like structures and are used for swimming. *Scylla serrata* has a smooth oval-shaped carapace and the dorsal shell is usually a dark olive/brown colour, with a visible H-shaped groove (Figure 4). They have a large, strong claw, nine sharp spines along the margins of the dorsal shell and also on the joints of the legs. *Scylla serrata* can reach carapace widths of ~25-28cm but widths of 15-20cm are most common.

![Figure 4. Scylla serrata / Mud crab / Mangrove crab / Kepiting bakau / MUD](www.seafdec.org.ph)

Mud crabs molt numerous times over their lifecycle, during which time they are vulnerable to predation and cannibalism (Mirera & Moksnes 2013). Mating occurs when the female in a molt stage, when she is in a soft-shell condition, and the male will protect her
during this time (Meynecke & Richards 2014). Adults and juveniles are often found in separate habitats (Dumas et al. 2012), with females migrating offshore during the spawning season to find habitats that are more chemically and thermally stable than closer inshore (Meynecke & Richards 2014).
2.3. Standard Operating Procedure, SOP, III – Sampling Design

Sampling is usually conducted in the supplier’s house. The catches from individual fisherwomen are collected from their landing sites and transported daily to the supplier’s house. The catches of each fisherwoman are kept separate until the supplier has paid for the catch. Sampling should be conducted before the crab catches are mixed. A maximum of twenty individual crabs should be randomly sampled from the catch of each fisherwoman.

This method is useful for sampling large amounts of data in a cheap and efficient manner. The use of this protocol for data collection purposes will generate information for use in estimating the crab stock status. Estimation of Spawning Potential Ratio (SPR (Hordyk et al. 2015)) can be used in determining the status of crab stocks. This sampling method requires the length or width frequency of the brood stock found in the population. This method is useful as it does not have a high data demand.
2.4. Standard Operating Procedure, SOP, IV – Carapace width measurements

The carapace is the hard-shelled dorsal side of a crab. Length measurements of individual crabs are measured as carapace width. Carapace width is a measurement across the widest part of the dorsal side of the crab, recorded using a calipers (Figure 5). Carapace length measurements are not recorded with this protocol. The front of the calipers is placed at one side of the crab carapace and the movable section is extended to reach directly across to the opposite side. The carapace width is recorded to the nearest mm, i.e. a carapace width of 15.5cm is recorded as 155mm.

Figure 5. Standard carapace width and length measurements of individual crabs.
2.5. Standard Operating Procedure, SOP, V – Sex and maturity level

The staff must distinguish between male and female crabs and, where possible, identify the maturity level of individuals. To identify the sex and the maturity level, look at the abdominal. Males will have a narrow triangular shaped abdominal flap whereas females will have a larger rounded abdominal flap, which may be a darker colour than the rest of the belly (Figure 6).

![Figure 6. Male and female Scylla serrata.](www.feveravenue.com)

Currently there is little information on the external characteristics of *Scylla serrata* maturity levels. Usually, immature females will have a small, pale abdominal flap and mature females will have a darker, larger, more rounded abdominal flap (Figure 7). Immature females should be assigned a maturity level ‘I’ and mature, non-berried females should be assigned a maturity level of ‘M’. Berried females, those with visible eggs in the abdominal flap, should be assigned a maturity level of ‘B’. The presence of mating scars on males may be an indication of maturity (Knuckey 1996). Mating scars occur during the precopulatory embrace between males and females and are visible on the abdominal and on the forward walking legs. They are usually visible on large individuals, indicating maturity. However, the absence of mating scars from a large individual does not mean the individual is immature as the scars disappear after each molt (Knuckey 1996).
Figure 7. Abdomens of (a) immature, (b) mature female and (c) mature male *Scylla serrata*.
2.6. Standard Operating Procedure, SOP, VI – Bait Data

Eel is the main bait used, with fish used on rare occasions. Each eel is cut into smaller pieces and can be used to bait multiple traps. Sometimes fish or leftover food is used to bait the traps but the eels are the preferred bait. Artificial bait is not used in this fishery. The bait fishery should be regarded as a separate fishery from the main target fishery and undergo a separate evaluation. To determine whether the bait species is at risk of overexploitation, a risk-based assessment should be conducted. If a stock is considered at risk, mitigation measures should be designed and implemented. To conduct the bait risk-based assessment, the following data is required for each species used as bait during a fishing trip:

- Species
- Gear used
- Location of capture
- Total weight
Chapter 3 – Data Collection Process

This section focuses on the collection process of fishery-dependent data from Indonesian landing sites for use in stock assessments. This data will be the basis for designing improved management systems that will move Indonesian mud crab fisheries towards sustainability. The process of uploading the data to I-Fish is described below.

In collaboration with district DKP and the owner / supplier of the vessels, the following vessel data should be recorded:

- vessel name
- captain name
- origin
- registration number
- vessel size class (GT)
- engine capacity (HP)
- number of fishermen employed
- gear used
- main fishing ground
- gear used
- main fishing ground

This process is conducted annually in most ports, through an automatic renewal system for registration, which may result in vessel/gears changes being unrecorded. Therefore this information should be recorded at the start of each year for each vessel participating in data collection activities.

3.1. Daily Port Sampling Form

The daily port sampling form is used to collect data from unloading events from individual vessels on a daily basis. One form is used per vessel per day. The following is a description of the data that should be recorded in each section of the port sampling form, (the port sampling form can be found in Appendix I):

3.2. Data storage and analysis

All data collected in these forms will be checked by the site supervisor, who then enter the data into spreadsheets on a computer every day. Data are entered into spreadsheets on the same day that they are collected to ensure discrepancies or data errors can be addressed and corrected while the information is still fresh. The site supervisor will then upload the data to I-Fish every month.

The sampled data can be analysed to create graphs and tables showing different types of information, such as:

a. Total produksi per alat tangkap
b. Total produksi per kategori spesies
c. Cakupan Sampling dari total produksi
d. Komposisi tangkapan spesies target
e. Komposisi tangkapan dari total tangkapan
f. Komposisi spesies tangkapan
g. Hubungan Panjang / berat spesies target (MUD)
h. Tangkapan per Upaya Unit (Kg / L bahan bakar)
i. Tangkapan per Upaya Unit (Kg / Jam (hari) di laut)
j. Produktivitas per Fishing Ground (FG)
k. Produktivitas per WPP
l. Kapasitas per Site (jumlah kapal aktif per kategori GT)

These graphs and tables can be shared with stakeholders using the I-Fish automatic reporting system and used for discussion at the DMC meetings.

To be finalised with more details when the reporting system is developed before the end of the project.
